Comments, bibliography, etc.

The stock of European hake was assumed in the boundaries of the whole GSA 18 where it inhabits depths from several meters in the coastal area down to 800 m in the South Adriatic Pit. For the evaluation of hake stock status in GSA 18 different methods and different sources of data (MEDITS data 1994-2010, selectivity experiments, DCF 2007-2010) have been used. Regarding the methods, the SURBA software (Needle, 2003), the ALADYM model (Lembo et al., 2009) and the VIT software (Leonart and Salat, 1997) were used. In ALADYM mortality levels and harvesting strategies are used to forecast the effects on the population metrics (accounting for cohort structure) and simulated catches, thus even different harvesting strategies from those actually assessed can be evaluated. The current level of the spawning stock vs. the level at $F = 0$ can be also estimated. The LCA (or pseudocohort analysis age-based) as implemented in VIT allows to perform a length cohort analysis under the steady state assumption and thus the fishing mortality vector is estimated. In addition, the Y/R analysis implemented in the software allows the calculation of the Biological Reference Points $F_{0.1}$ and F_{max} . A transition analysis with VIT was performed, in order to evaluate the impact of different exploitation scenarios. Finally, all the methods for the evaluation are discussed and used in a complementary and integrated way, in order to exploit the advantage of a multi-methods and multi-data approach.

Comments, bibliography, etc.

To account for uncertainty in life history profile of European hake a sensitivity analysis was performed using two scenarios of growth: slow and fast growth. For both scenarios the analyses are conducted for sex combined. Natural mortality vectors for the two scenarios were obtained applying the Prodbiom method (Abella et al., 1997).

Comments

Mature females were found all year round with peaks in early winter and late spring. A proxy of size at first maturity (SAMED, 2002) using the average length at stage 2 (females with gonads at developing stage) indicated an average length of about 29 cm. According to the data obtained in the DCF framework, the proportion of mature females (fish belonging to the maturity stage 2 onwards) allowed to estimate a maturity ogive with a size at first maturity varying around 33.4 (± 0.15 cm) (maturity range 3.8 ± 0.16 cm). The observed maximum lengths of European hake were 93.5 cm for females and 66.5 cm for males both registered during Medits samplings. In the commercial sampling also a female of 93.5 cm length was observed in 2009. In the DCF framework the growth has been studied ageing fish by otolith readings using the whole sagitta and thin sections for older individuals. Length frequency distributions were also analyzed using techniques as Batthacharya for separation of modal components. The estimates of von Bertalanffy growth parameters were obtained for sex combined from average length at age using an iterative non-linear procedure that minimises the sum of the square differences between observed and expected values.

To account for uncertainty in life history profile of European hake a sensitivity analysis was performed using two scenarios of growth for sex combined: Linf = 95, k = 0.14 and t0 = -0.4, (slow scenario); Linf=104 cm, k=0.2, t0= -0.01 (SGMED, 2010 (fast scenario). Length-weight relationship: a=0.0043, b=3.155 for both scenarios.

The plus group 5+ and 4+ were used respectively for slow and fast growth.

Age	0	1	2	3	4	5+
M (slow)	0.76	0.42	0.30	0.25	0.25	0.25

Weight (kg) (fast)	0.01	0.14	0.53	1.15	2.35

Comments

M. merluccius spawns throughout the year, but with different intensities. The spawning peaks are in the summer and winter periods (Zupanovic, 1968; Ungaro et al., 1993; Donnalioia, 2009). Recent estimates of the batch fecundity (Donnalioia, 2009) reported higher values in comparison to the fecundity reported by Morua et al. (2006) for the Atlantic Sea and Recasens et al. (2008) for the Northern Tyrrhenian Sea. Karlovac (1965) recorded young hake larvae from October to June, the highest numbers were recorded in January and February. Larvae and post-larvae were mainly distributed between 40 and 200 m; the highest number of individuals was caught mainly between 50 and 100 m. Recruitment peaks in the winter and late spring (Ungaro et al., 1993; Donnalioia, 2009). The geographical distribution pattern of European hake has been studied in the area using trawl-survey data and the geostatistical methods. In the GSA18 nursery areas have been localised off Gargano promontory along the west side (100-200 m depth) and in the southern part of Albanian coasts (Frattoni and Paolini, 1995; Lembo et al., 2000; Carlucci et al., 2009).

Kirinčić and Lepetić (1955) and De Zio et al. (1998) investigated the catch size structure from the bottom long-line fishery in the Southern Adriatic. The average total length of the European hake was 58.6 cm (Kirinčić and Lepetić, 1955), while De Zio et al. (1998) found a median total length of 70 cm. The average catch rate was 5.6 specimens per 100 hooks.

Comments

The fleet data are referred to the whole GSA and are related to the year 2007 (GFCM Statistical Bulletin 2008). Catch data above reported for the west side are referred to the year 2010 (DCF data). The operational unit ITA18E0333-HKE and ITA18E0333-HKE include also demersal slope fishing (mixed demersal according to DCF classification).

The catch data from the whole GSA18 including the east side are below reported:

OpUnit 1* ITA 18 C 07 33 - HKE

Regulations in force and degree of observance of regulations

Management regulations are based on technical measures related to the height and length of the gears as well as the mesh size opening, minimum landing sizes and number of fishing licenses for the fleet.

Accompanying species

European hake is mostly targeted by trawlers, and to a lesser extent by small scale fisheries using nets and bottom long-lines. Fishing grounds are located along the coasts of the whole GSA offshore 50 m depth. *M. barbatus*, *M. surmuletus*, *S. officinalis*, *O. vulgaris*, *E. cirrhosa* and *P. erythrinus* may co-occur in the catches.

Data source*	EU data Collection framework	OpUnit 2*	ITA 18 E 03 33 - HKE
--------------	------------------------------	-----------	----------------------

Regulations in force and degree of observance of regulations

Management regulations are based on technical measures, closed number of fishing licenses for the fleet and area limitation (distance from the coast and depth). In order to limit the over-capacity of fishing fleet, the Italian fishing capacity has been gradually reduced. In 2008 a management plan was adopted. Other measures on which the management regulations are based regards technical measures (mesh size), minimum landing sizes (EC 1967/06) and seasonal fishing ban along the west side.

Accompanying species

Fishing grounds are located along the coasts of the whole GSA offshore 50 m depth or 3 miles from the coast. Catches from trawlers are from a depth range between 50-60 and 500 m and hake occurs with other important commercial species as *Illex coindetii*, *M. barbatus*, *P. longirostris*, *Eledone spp.*, *Todaropsis eblanae*, *Lophius spp.*, *Pagellus spp.*, *P. blennoides*, *N. norvegicus*.

Comments

These results are referred to the slow growth scenario for 2010.
A first exercise for an evaluation at the whole GSA level based on preliminary data of commercial landings from Albanian trawlers for 2010 and also of length-frequency distribution from Montenegrin trawlers in 2010 was accomplished.
The assumption that length-frequency distribution (LFD) of Albanian commercial catch was similar to the Italian LFD has been made, due to the unavailability of suitable LFD data; therefore, the LFD of Italian trawlers was raised to the Albanian production of trawlers. The VPA and the Y/R analysis have been performed for 4 fleet segments: Italian longlines, Italian trawlers, Albanian trawlers and Montenegrin trawlers.

Comments

These results are referred to the fast growth scenario for 2010.
A first exercise for an evaluation at the whole GSA level based on preliminary data of commercial landings from Albanian trawlers for 2010 and also of length-frequency distribution from Montenegrin trawlers in 2010 was accomplished.
The assumption that length-frequency distribution (LFD) of Albanian commercial catch was similar to the Italian LFD has been made, due to the unavailability of suitable LFD data; therefore, the LFD of Italian trawlers was raised to the Albanian production of trawlers. The VPA and the Y/R analysis have been performed for 4 fleet segments: Italian longlines, Italian trawlers, Albanian trawlers and Montenegrin trawlers.

Comments

These results are referred to the slow growth scenario and are an average among 2007-2009. An assessment based on the LCA analysis was performed for the west side of the GSA 18 for years 2007, 2008, 2009 using the VIT software. To perform LCA, using VIT4win, landings data for years 2007-2009 sent for Mediterranean and Black Sea data call - 2011 were used. The complete results for each year are in sheet A3/3.

Other assessment methods

SURBA

SURBA software was applied to get a first evaluation of the mortality and recruitment levels, using MEDITS abundance (N/km²) estimates by length and then age sliced using the 2 sets of parameters (slow and fast growth) used for LCA.

All the other parameters were those reported in the sheets 0 and B. Catchability was set as follows:

Age		0	1	2	3	4	5+
q (slow)		0.90	1.00	1.00	1.00	0.75	0.75
q (fast)	0.90	1.00	1.00	0.75	0.75		

The age groups derived from the age slicing are reported in the table below.

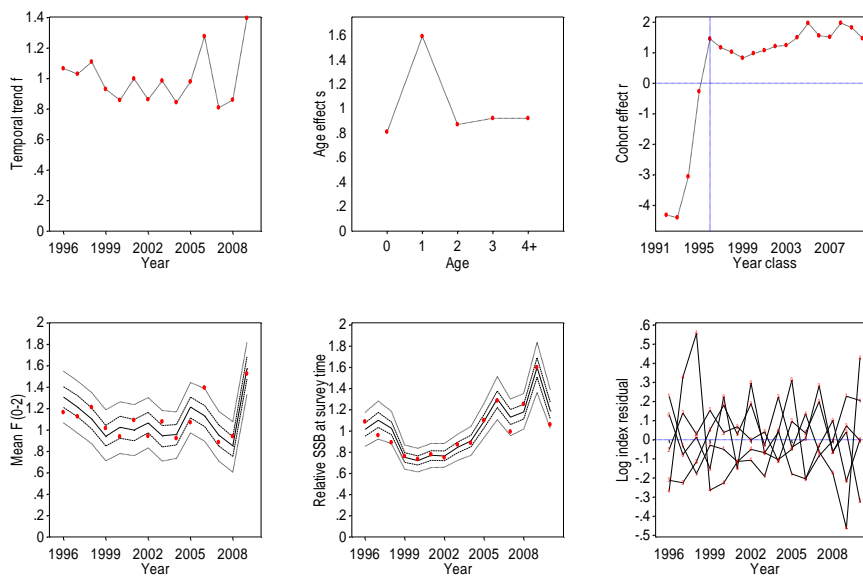

‘Slow’ age groups

Year	0	1	2	3	4	5+
1996	460	231	33	4	1	2
1997	272	200	39	5	1	2
1998	254	167	15	3	1	2
1999	165	111	14	2	1	2
2000	367	121	15	2	1	2
2001	256	128	11	2	1	1
2002	632	96	16	2	1	1
2003	282	113	21	3	1	1

Results

On the overall, results from SURBA highlight a level of Z from 1.2 to 1.6 under the slow growth and a range of 1.6-2.1 under the fast growth scenario, while F is respectively 0.7-1.2 and 0.8-1.4, as expected according to an accelerated dynamics is higher in the fast growth scenario.

Trends in various stock parameters from SURBA, hake GSA18, fast growth pattern

Other assessment methods

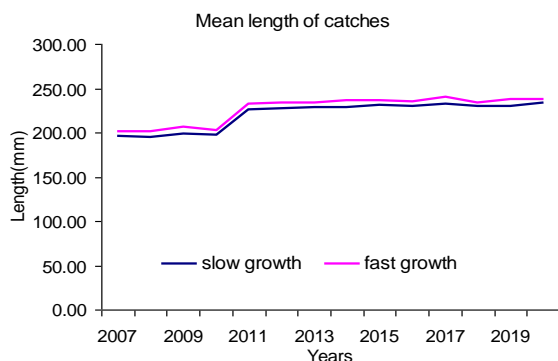

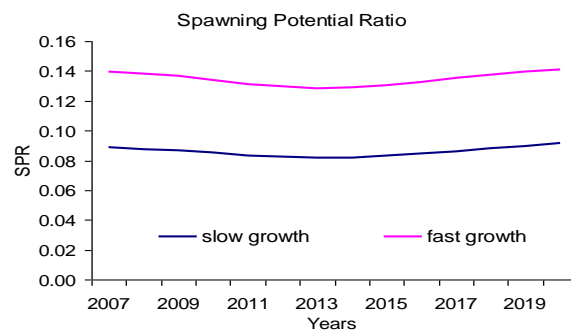

ALADYM

Aladym model was applied to evaluate the consequences of the mortality and harvesting strategies on the population metrics and simulated catches, using an hindcasting approach. The total mortality and the recruitment estimated by VIT for 2007-2010 were used to parameterize the model. For 2010 the estimates of from the whole area were used. To estimate Z and recruitment in 2011 a geometric mean among 2007-2010 was calculated.

The fleet fishing selectivity was simulated using an ogive model with the following parameters: Lc=12cm; selection range (SR) 1 cm. This was coupled with a deselection ogive with 50% deselection size at 40 cm and a deselection range of 1 cm, to account for possible avoidance/reduced availability of older fish. Also the coefficient of monthly activity of the fleet was considered in the simulation. From 2012 the enforcement of 50 mm mesh size was assumed widely applied. Lc = 16 cm (SR = 1 cm) from 2012 until the end of simulation (2020) was set.

In addition a simulation was also performed from 2012 to 2020 implementing possible management measure to fulfill the target reference points. A reduction of the fishing activity was set, reducing of 40% the current monthly level and assuming a fishing ban of 2 months with a 30% activity of the current levels. In addition a further reduction of 15% of mortality was simulated from 2014.

Aladym, results of simulation from 2007 to 2020, slow and fast scenario, with increase of Lc from 12 to 16 cm (graphs 1-3). Aladym, results of simulation from 2007 to 2020, enforcing mesh size, reducing fishing activity by month and further reducing fishing mortality from 2014, fast growth scenario (graph 4).

Other assessment methods

VIT- Transition analysis

The transition analysis using VIT software assuming a steady state was performed, simulating eight different scenarios of gradual reduction of fishing mortality to the target BRP F0.1 and the limit BRP Fmax. The landing data from Italy, Albania and Montenegro of 2010 were used:
 Scenario 1.a: Reduction to F0.1 level until 2015, with a gradual annual decrease of 29% for slow growth.

Scenario 1.b: Reduction to F0.1 level until 2015, with a gradual annual decrease of 30% for fast growth.

Scenario 2.a: Reduction to Fmax level until 2015, with a gradual decrease of 24% for slow growth.

Scenario 2.b: Reduction to Fmax level until 2015, with a gradual decrease 25% for fast growth.

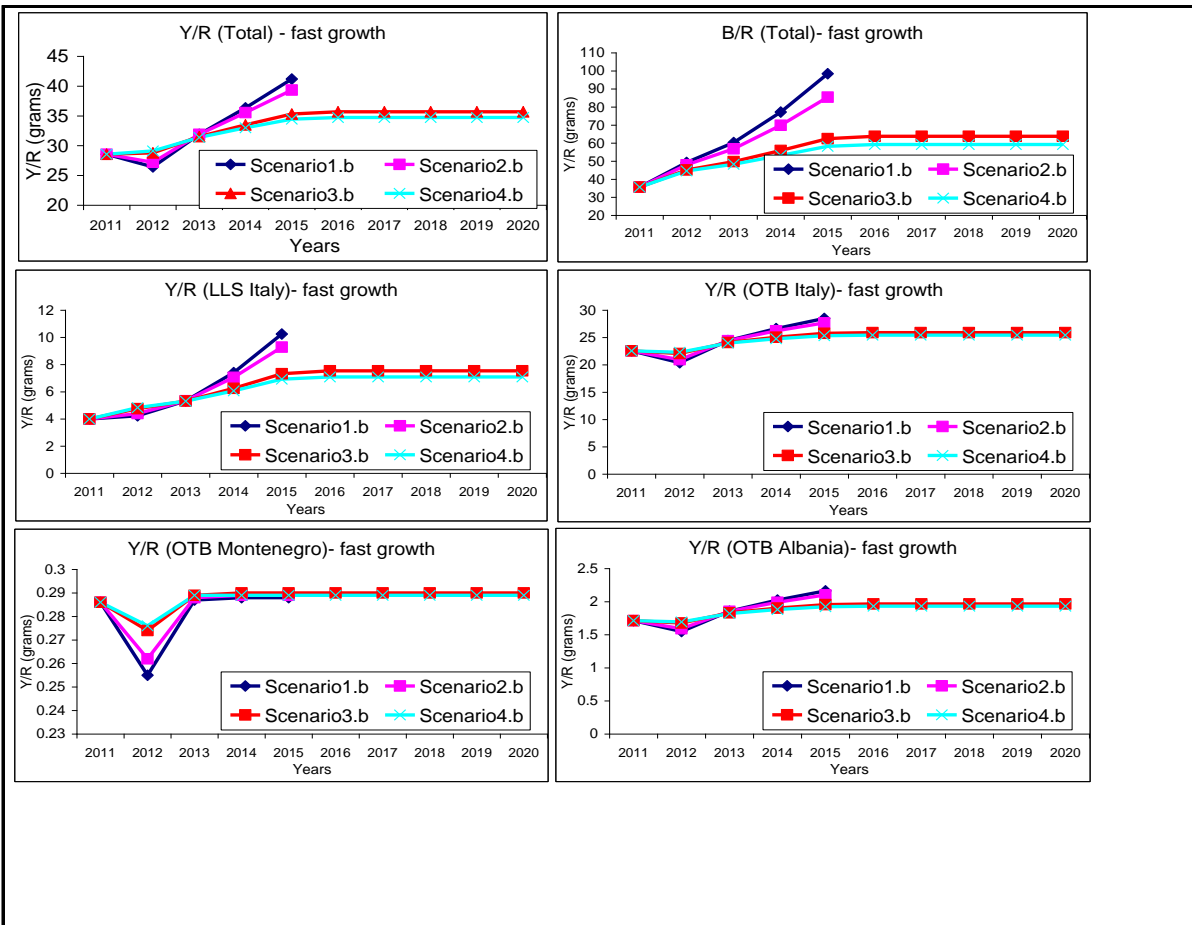

Scenario 3.a: Reduction to F0.1 level until 2020, with a gradual annual decrease of 14% for slow growth.

Scenario 3.b: Reduction to F0.1 level until 2020, with a gradual annual decrease 15% for fast growth.

Scenario 4.a: Reduction to Fmax level until 2020, with a gradual annual decrease of about 12% for slow growth.

Scenario 4.b: Reduction to Fmax level until 2020, with a gradual annual decrease of 12% for fast growth.

The results of the fast growth scenario are reported below.

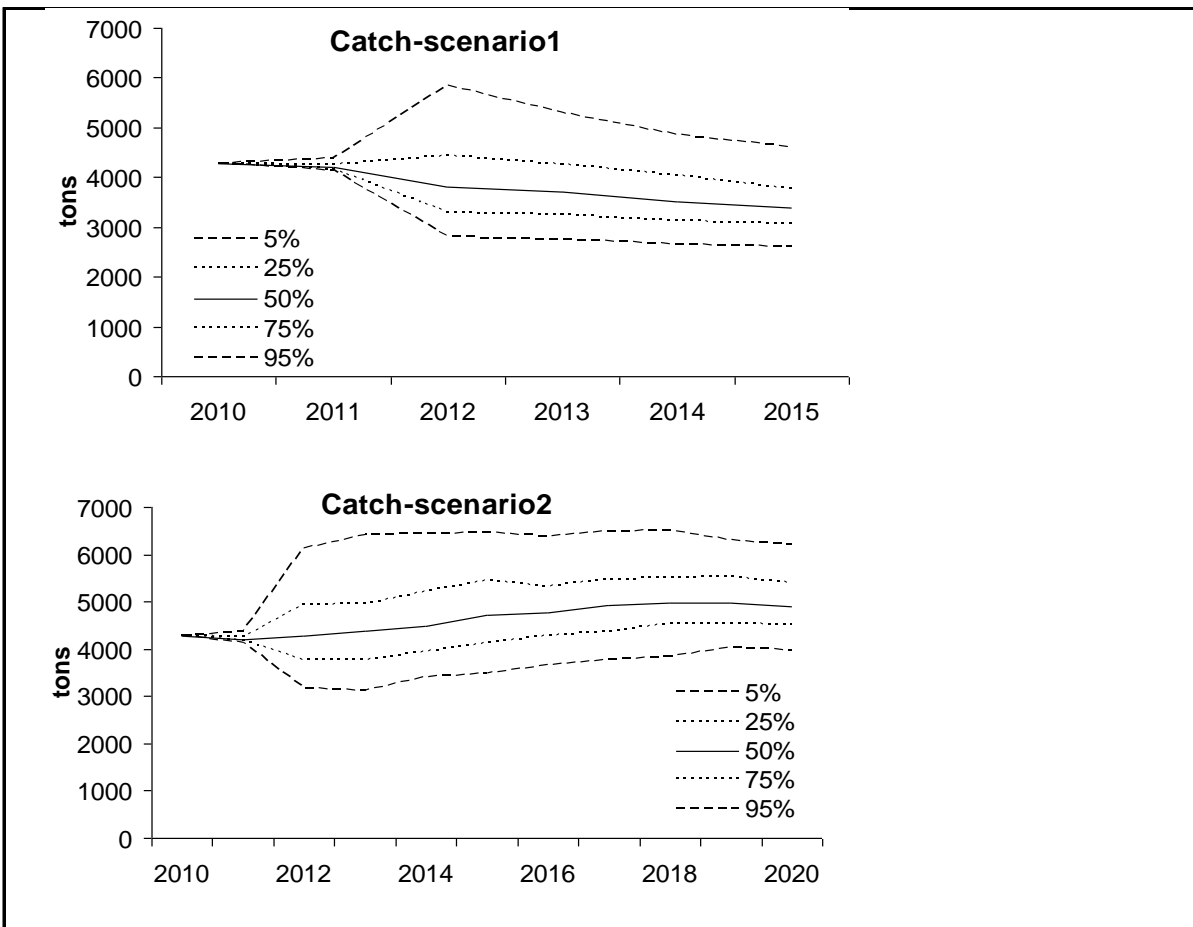

Other assessment methods

Medium term forecast R-routine (SGMED, 2010)

A medium term forecast was also performed, using the R routine developed during SGMED 2010.

Two scenarios have been projected, starting from a fishing level equal to the F current calculated by LCA (VIT) in the fast scenario for 2010 ($F = 0.86$) in order to achieve $F_{0.1}$ until 2015 (annual reduction of 30%, scenario1) and until 2020 (annual reduction of 15%, scenario 2).

Stock Status* Use one (or both) of the following two systems for the stock assessment status description

Unidimensional	<input type="radio"/>	? - (or blank) Not known or uncertain. Not much information is available to make a judgment;
	<input type="radio"/>	U - Underexploited, undeveloped or new fishery. Believed to have a significant potential for expansion in total production;
	<input type="radio"/>	M - Moderately exploited, exploited with a low level of fishing effort. Believed to have some limited potential for expansion in total production;
	<input type="radio"/>	F - Fully exploited. The fishery is operating at or close to an optimal yield level, with no expected room for further expansion;
	<input checked="" type="radio"/>	O - Overexploited. The fishery is being exploited at above a level which is believed to be sustainable in the long term, with no potential room for further expansion and a higher risk of stock depletion/collapse;
	<input type="radio"/>	D - Depleted. Catches are well below historical levels, irrespective of the amount of fishing effort exerted;
	<input type="radio"/>	R - Recovering. Catches are again increasing after having been depleted or a collapse from a previous;

Bidimensional	Exploitation rate		Stock abundance	
	<input type="radio"/>	No or low fishing	<input type="radio"/>	Virgin or high abundance
	<input type="radio"/>	Moderate fishing	<input type="radio"/>	Intermediate abundance
	<input checked="" type="radio"/>	High fishing mortality	<input type="radio"/>	Low abundance
	<input type="radio"/>	Uncertain / Not assessed	<input type="radio"/>	Depleted
			<input type="radio"/>	Uncertain / Not assessed

Comments

After the exceptional peak of recruitment observed in 2005, the recruit abundance reached comparable levels as in the years before 2005. However a remarkable abundance of recruits was also observed in 2008. Given the results of the present analysis, the stock of hake appears overexploited since the current fishing mortality is higher than $F_{0.1}$ and F_{max} .

Objectives and recommendations

Code: HKE1811Spe

Management advice and recommendations*

Given the results from this analysis, on 2010 based on the whole information from the area, it is necessary to consider that a remarkable reduction of the fishing mortality is necessary to allow the achievement of both the limit and target reference points, regardless of the growth pattern of the species. The limit and target BRPs $F_{0.1}$ and F_{max} can be gradually achieved by multiannual management plans that will require a more sharp reduction in the short term than in the medium term. However, it should also be taken into account that a more gradual reduction will very likely imply lower social and economic costs compared to a sharp reduction, without hampering the sustainability objective.

Simulations also show that the objectives of a more sustainable harvest strategy could be achieved with a multiannual plan that foresees a reduction of fishing mortality through fishing activity limitations and possibly fishing capacity decreasing.

It is however necessary to consider in the eventual implementation of multiannual management plans that most of the fishing mortality is derived from the Italian bottom trawlers that represent about 85% of the total F in the GSA and that of the Italian longlines accounting for about 7-8%, with an overall percentage of about 92-93%, while Montenegrin trawlers account only for about 1% of the F exerted on the GSA and Albanian trawlers of about 6.5%. Moreover, the production of hake in GSA 18 is split in 14% caught by Italian longlines, 79% by Italian trawlers, about 1% by Montenegrin trawlers and about 6% by Albania trawlers.

Proportion of F level by fleet for slow and fast growth scenarios

F - proportion

Growth	LLS it	OTB it	OTB Mon	OTB Alb
slow	0.069	0.854	0.011	0.065
fast	0.084	0.841	0.011	0.064

Advice for scientific research*

Supporting of tagging experiments of hake to improve knowledge on the species growth at larger scale and improving knowledge on hake behaviour at different life-stages.
Introduce a second annual scientific survey campaign in autumn to improve temporal resolution of survey data, in particular data on recruitment and mortality.

Abstract for SCSA reporting

Authors Spedicato M.T.1, Bitetto I.1, Lembo G.1, Carbonara P.1, Casciaro L.1, Facchini M.T.1, Milone N.2, Ceriola L.2, **Year** 2011

Source: -

Geographical Sub-Area 18 - Southern Adriatic Sea

Fisheries (brief description of the fishery)*

Merluccius merluccius is a high-score priority species in the Geographical Sub Area 18 that remarkably contribute to the fishery production.
Fishing grounds are located on the soft bottoms of continental shelves and the upper part of continental slope along the coasts of the whole GSA. Catches from trawlers are from a depth range between 50-60 and 500 m and hake occurs with other important commercial species as *Illex coindetii*, *M. barbatus*, *P. longirostris*, *Eledone* spp., *Todaropsis eblanae*, *Lophius* spp., *Pagellus* spp., *P. blennoides*, *N. norvegicus*.
Most part of the landings of hake are from trawlers.
In 2010 the landings of hake were about 4020 tons in the west side with the higher production from trawlers (3400 tons) followed by longliners (601 tons) and by the gillnets (19 tons). Along the east side the production from trawlers in 2010 was about 276 tons divided by 36 tons from Montenegro and 240 tons from Albania.

Source of management advice*

(brief description of material -data- and methods used for the assessment)

For the evaluation of hake stock status in GSA 18 different methods and different sources of data (fishery dependent and fishery independent) have been used. SURBA software, ALADYM model and VIT software were used. All the methods for the evaluation are discussed and used in a complementary and integrated way, in order to exploit the advantage of a multi-methods and multi-data approach. To account for uncertainty in life history profile of European hake a sensitivity analysis was performed using two scenarios of growth: slow and fast growth. For both scenarios the analyses are conducted for sex combined. Natural mortality vector for the two scenarios were obtained applying the Prodbiom method.

Stock Status*

O - Overexploited. The fishery is being exploited at above a level which is believed to be sustainable in the long term, with no potential room for further expansion and a higher risk of stock depletion/collapse;

Exploitation rate

Stock abundance

High fishing mortality
